NMix

Parametrisation

The N-Mixture distribution is a Poisson mixture of the Binomials, as

$$Prob(y) = \sum_{n=y}^{\infty} \binom{n}{y} p^n (1-p)^{n-y} \times \frac{\lambda^n}{n!} \exp(-\lambda)$$

for responses y = 0, 1, 2, ..., n, where n is Poisson number of trials, and p is probability of success. Replicated reponses $y_1, y_2, ..., y_r$, are iid from the Binomial with the same p, conditioned on the same p from the Poisson,

$$\operatorname{Prob}(y_1, \dots, y_r) = \sum_{n=\max\{y_1, \dots, y_r\}}^{\infty} \left\{ \prod_{i=1}^r \binom{n}{y_i} p^n (1-p)^{n-y_i} \right\} \times \frac{\lambda^n}{n!} \exp(-\lambda)$$

Link-function

The probability p is linked to the linear predictor by

$$p(\eta) = \frac{\exp(\eta)}{1 + \exp(\eta)}$$

for the default logit link, while λ depends on fixed covariates

$$\log(\lambda) = \sum_{j=1}^{m} \beta_j x_j$$

with one vector of covariates for each observation. m can be maximum 15 and minimum 1.

Hyperparameters

The parameters $\theta_1 = \beta_1, \theta_2 = \beta_2, \dots, \theta_m = \beta_m$.

Specification

- family = nmix
- Required arguments: the response *Y* and covariates *X* as inla.mdata(Y, X [, additional.covariates])

The response is a matrix where each row are replicates, where responses that are NA's are ignored. The covariates is one or many vectors, matrices or data frames. Each row of the covariates $(x_{i1}, x_{i2}, \ldots, x_{im})$ defines the covariates used for the *i*'th response(s) (the *i*'th row of Y). Note that $\beta_{m+1}, \ldots, \beta_{15}$ are fixed to zero.

Example

In the following example we estimate the parameters in a simulated example with replications.

```
nrep.max = 5
n = 50
y = matrix(NA, n, nrep.max)
x = c()
xx = c()
intercept = 1
for(i in 1:n) {
    local.x = runif(1) - 0.5
    lambda = exp(2 + local.x)
    N = rpois(1, lambda)
    local.xx = runif(1) - 0.5
    eta = intercept + local.xx
    p = \exp(eta)/(\exp(eta) + 1)
    ## sample the number of replications
    nr = sample(1:nrep.max, 1)
    ## and sample these. note that 'y' is initialized with NA's,
    ## so if nr < nrep.max, then
    ## y[i,(nr+1):nrep.max] would be NA.
    y[i, 1:nr] = rbinom(nr, size = N, prob = p)
```
